# Solution Verification

Boundary value problem ( $\Omega$ ) is a polygonal domain and  $n = 2$  or  $3$  :

$$L[u(x)] = f(x), \quad x \in \Omega \subset \mathbb{R}^n, \quad u = g \text{ on } \partial\Omega.$$

Assume that the PDE problem is well posed and has a unique solution. We consider an approximation on a family of meshes  $M(h)$  parameterized by  $h > 0$  a small parameter.

We denote symbolically the corresponding family of linear systems

$$A_h U_h = F_h.$$

Let  $p_h$  denotes the projection of the continuous solution  $u$  onto the mesh  $M(h)$ . We assume a priori that ( $\|\cdot\|$  is a given discrete norm):

$$\|U_h - p_h(u)\| \rightarrow 0, \text{ as } h \rightarrow 0,$$

$$\|U_h - p_h(u)\| \rightarrow 0, \text{ as } h \rightarrow 0,$$

## Manufactured solution

$$f(x) = L[u(x)]$$

- Polynomial solution to verify the code.
  - Test each term of the equation.
  - Useful for parallel codes
- Use of symbolic manipulation languages
- Constraint by conservation of physical quantities
- Principle of nearby exact solution (C.J.Roy and M.M.Hopkins).
- Possible use of image analysis on experimental data.

### Conclusion

# Optimized Extrapolation Technique

- Let  $M(h_1)$  and  $M(h_2)$  be two  $\neq$  meshes used to build two approximations  $U_1$  and  $U_2$  of the PDE problem.
- A consistent linear extrapolation writes

$$\alpha U_1 + (1 - \alpha) U_2,$$

where  $\alpha$  is a weight function.

- In classical Richardson Extrapolation (RE)  $\alpha$  is a constant.
- In our optimized extrapolation method  $\alpha$  is a function solution of the following optimization problem:

$P_\alpha$ : Find  $\alpha \in \Lambda(\Omega) \subset L_\infty$  such that  $G(\alpha U_1 + (1 - \alpha) U_2)$  is minimum.

- For computational efficiency,  $\Lambda(\Omega)$  should be a finite vector space of very small dimension compared to the dimension of  $A_h$ .

## Conclusion

# General Idea

- One can choose to work with a posteriori FE error estimates:
  - Equilibrated residual method for FE .- see Ainsworth & Oden and ref.
  - A posteriori Finite-Element free constant output bounds - see Patera and ref.

**From now on, and to make our technique general, we will work with discrete value functions and discrete norms: Why is it possible?**

- Our ambition: a numerical estimate on  $\|U_j - U_\infty\|$ ,  $j = 1, 2$ , without computing  $U_\infty$ .
- $M(h_\infty)$  should capture a priori all the scales needed.
- In practice  $h_\infty \ll h_1, h_2$ .
- The solution  $U_j$  can be verified, assuming convergence of the approximation method, i.e  $U_\infty \rightarrow u$ , as  $h_\infty \rightarrow 0$ .
- Reuse extensive knowledge of Physicist and Asymptotic Analysis.
- Reuse Stability Theory from Linear Algebra.

## Conclusion

# Practical Consequences

- Both coarse grid solutions  $U_1$  and  $U_2$  must be projected onto  $M(h_\infty)$ . Notation:  $\tilde{U}_1$  and  $\tilde{U}_2$ .

- The objective function is a discrete norm of the residual:

$$G(U^\alpha) = \|A_{h_\infty} U^\alpha - F_{h_\infty}\|, \text{ where } U^\alpha = \alpha \tilde{U}_1 + (1 - \alpha) \tilde{U}_2.$$

The Optimized Extrapolated Solution (OES) if it exists, is denoted  $V_e = \alpha_e U_1 + (1 - \alpha_e) U_2$ .

- The choice of the discrete norm depends on the property of the solution.
- One can choose to work in a subspace:
  - Estimate on a functional of the solution.
  - Estimate in subdomain.

Algorithm/Result with No detail code knowledge

## Conclusion

Cancelation phenomenon: surface plot of space dependent convergence order approximation for  $\omega - \psi$  code with  $Re=100$ .

## Three level methods (2)

- There are subset of  $\Omega$  where  $\tilde{U}_1 - \tilde{U}_2 \ll h^k$ , with  $k$  expected order of convergence.

- Optimized two-level extrapolation problem is ill posed.

**Three levels OES** Find  $\alpha, \beta \in \Lambda(\Omega) \subset L_\infty$  such that

$G(\alpha U_1 + \beta U_2 + (1 - \alpha - \beta) U_3)$  is minimum.

- If all  $U_j$ ,  $j = 1..3$ , coincide at the same space location there is either no local convergence or all solutions  $U_j$  are exact.

- Robustness of the method should come from the fact that we do not suppose a priori any asymptotic formula on the convergence rate of the numerical method as opposed to RE.

Conclusion

---

# A Posteriori Error

# General Principle (1)

- Let us assume that  $V_e$  exists and has been computed.
- Let  $U_j$  be one of the coarse grid approximations; We look for a global a posteriori estimate of the error

$$\|\tilde{U}_j - p_h(u)\|.$$

- Recovery method:

$$\text{IF } \|V_e - p_h(u)\|_2 \ll \|\tilde{U}_j - p_h(u)\|_2,$$

$$\text{THEN } \|\tilde{U}_j - V_e\|_2 \sim \|\tilde{U}_j - p_h(u)\|_2$$

- Heuristic: provides a good *lower* bound on the error in our numerical experiments with steady incompressible Navier Stokes (NS).
- But there is no guarantee that a smaller residual for  $V_e$  than for  $U_2$  on the fine grid  $M(h_\infty)$  leads to a smaller error.

Conclusion

- From a stability estimate with the discrete operator:

$$\|V_e - U_\infty\| < \mu_\infty G(V_e), \text{ where } \mu \geq \|(A_{h_\infty})^{-1}\|.$$

we conclude

$$\|\tilde{U}_2 - U_\infty\|_2 < \mu G(V_e) + \|V_e - \tilde{U}_2\|_2.$$

- Uses extrapolation on  $\mu_1, \mu_2, \mu_3$  to get  $\approx \mu_\infty$ .
- $L_2$  norm: the estimate on  $\mu$  uses a standard eigenvalue iterative procedure to get the smallest eigenvalue.
- $L_1$  norm: see N J.Higham papers.
- Additional Test: Verify that the upper bound on  $\|U_\infty - U_2\|$  increases toward an asymptotic limit as  $M(h_\infty)$  gets finer. Feasible test because the fine grid solution is never computed in OES.

Conclusion

- Let  $(E, \|\cdot\|_E)$  and  $(F, \|\cdot\|_F)$  be two normed linear space,  $N \in L(E, F)$  be the operator corresponding to the CFD problem.

- Assuming the problem  $N(u) = s$  is well posed for  $s \in B(S, d)$ , and  $N(U_h) \in B(S, d)$ , for some discrete solution  $U_h$ .

- Defining  $\rho$  the residual and  $e$  the error, an upper bound of the error is given by

$$\|e\|_E \leq \|\rho\|_F (\|\nabla_s N^{-1}(S + \rho)\|_E + \frac{K}{2} \|\rho\|_F).$$

- Let  $\{b_i^E, i = 1..N\}$ , be a basis of  $E$ , and  $\varepsilon \in \mathbb{R}$  such that  $\varepsilon = o(1)$ .

- Let  $(V_i^\mp)_{i=1..N}$ , be the family of solutions of the following problems  $N(U_h \mp \varepsilon V_i) = S + \rho \mp \varepsilon b_i$ .

A Posteriori Error

- General Principle (1)
- General Principle (2)
- Stability estimate (1)
- **Stability estimate (2)**

Algorithm/Result with detail code knowledge

Algorithm/Result with No detail code knowledge

Conclusion

- We get from finite differences the approximation

$$C_{h_\infty} = \|\nabla_S N^{-1}(S + \rho)\| \approx \left\| \left( \frac{1}{2}(V_j^+ - V_j^-) \right)_{j=1..N} \right\| + O(\varepsilon^2).$$

- Fundamental tool: compact representation of the solution via a projection: trigonometric polynomial or wavelet or spectral elements for example.
- One get the error estimate in this smaller space only.
- The size of the space is fixed adaptively according to the quality of the approximation of trigonometric polynomial/wavelets of the FE solution!.
- Both stability estimate and OES construction relies on several hundred of residual/smoothing computation that are extremely fast and have embarrassing parallelism → distributed computing !!!

Conclusion

---

# Algorithm/Result with detail code knowledge

# General Principle(1)

- Assume that the operator is linear and the objective function is the discrete  $L_2$  norm of the residual.

- Let  $e_i, i = 1..m$  be a set of basis function of  $\Lambda(\Omega)$ .

The solution process can be decomposed into three steps.

- Step 1: interpolation of the coarse grid solution from  $M(h_j), j = 1..p$ , to  $M(h_\infty)$  and postprocessing to smooth out the "spurious modes".

- Step 2: evaluate the residual

$$R[e_i (\tilde{U}_j - \tilde{U}_{j+1})], i = 1..m, j = 1..p - 1,$$

and  $R[\tilde{U}_p]$  on the fine grid  $M(h_\infty)$ .

- Step 3: solution of the least square linear algebra problem that has  $m$  unknowns for each weight coefficient  $\alpha$  and  $\beta$ .

# General Principle(2)

● General Principle(1)

● General Principle(2)

●  $div(\rho \nabla u) = f$

● Error Estimate in  $L_2$  norm

Algorithm/Result with No detail  
code knowledge

---

Conclusion

---

- Compact representation of unknown weight functions:  $m$  is much lower than the number of grid points on any coarse grid used.
- Estimate on the number of iterates to regularized  $\tilde{U}_j, j = 1..p$
- Generalization to non-linear elliptic problems via a Newton like loop.
- Difficulties: A posteriori Error estimate depends then on the function used to linearized the operator.
- Generalization to  $L_1$  and  $L_\infty$  with appropriate minimization procedure.

$$\operatorname{div}(\rho \nabla u) = f$$

Conclusion

Let us denote  $N[u] = 0$  the supposedly well posed PDE problem to be solved, and its unsteady companion problem,  $\partial_t u = N[u]$ .

The algorithm is as follow:

- **Step 1 *Call coarse Mesh*** : We generate the (coarse) meshes  $G_1$  and  $G_2$ . If  $h_i$  is the average space step for the grid  $G_i$  we should have  $h_2 < h_1$  but this is not necessary.
- **Step 2 *Call fine Mesh*** : We generate a fine mesh  $G_\infty$  that is supposed to solve all the scales of the problem.  $G_\infty$  might be a structured mesh or not. We must have  $h_\infty \ll h_1, h_2$ .
- **Step 3 *Call Solver*** : We solve the problem on  $G_1$  and  $G_2$ , possibly in parallel. The solutions are denoted respectively  $u_1$  and  $u_2$  on  $G_1$  and  $G_2$ .

● Software Architecture

Conclusion

● **Step 4 Call Projection** : We project these coarse solutions  $u_1$  and  $u_2$  onto  $G_\infty$ . We denote these projections  $\tilde{u}_1^\infty$  and  $\tilde{u}_2^\infty$ .

● **Step 5 Create sample** : We create sample solutions  $u_\alpha^\infty = [\alpha\tilde{u}_1^\infty + (1 - \alpha)\tilde{u}_2^\infty]$ . We smooth out the spurious high frequency components of the build solution with few explicit time steps of  $\partial_t u = N(u)$  starting from the initial condition:  $u_\alpha^\infty$ . The choice of the Optimum Design Space in which  $\alpha$  is taken is one the main item of our research.

● **Step 6** We compute the best  $\alpha$  that minimizes the  $L_2$  norm of the residual. We may use a surface response technique.

# Benchmark Problems

- Laminar flow over a backward facing step

The flow problem has the following characteristics:

Density	1	Length of the pipe	10
Viscosity	0.01	Inflow diameter	1
Maximum Inflow Velocity	U=1	Outflow diameter	2
Reynold Number	500		

- Heat Transfer in a composite material (Sandia Nat. Lab.)

$$\frac{\partial}{\partial x_i} (k_{ij}(T)) \frac{\partial T}{\partial x_j} + Q(T) = 0 \text{ in } \Omega \times (0, T)$$

The boundary conditions are of robin type to describe radiations effects. Remark : The problem is very stiff and the solution is near discontinuous between material.
